Abstract

Let $G$ be a reductive algebraic group scheme defined over $\mathbb{F}_p$ and $G_1$ be the first Frobenius kernel. For any dominant weight $\lambda$, one can construct the Weyl module $V(\lambda)$. When $p$ is a good prime for $G$, the $G_1$-support variety of $V(\lambda)$ was computed by Nakano, Parshall and Vella in [D.K. Nakano, B.J. Parshall, D.C. Vella, Support varieties for algebraic groups, J. Reine Angew. Math. 547 (2002) 15–49]. We complete this calculation by computing the $G_1$-supports of the Weyl modules over fields of bad characteristic.

Keywords: Cohomology; Support varieties; Weyl modules

1. Introduction

1.1. Support varieties were introduced in the pioneering work of Alperin [A] and Carlson [Ca1,Ca2] nearly 25 years ago as a method to study complexes and resolutions of modules over group algebras. Since that time these ideas have been extended to encompass restricted Lie algebras by Friedlander and Parshall [FP], finite-dimensional sub Hopf algebras of the Steenrod algebra by Nakano and Palmieri [NPal], infinitesimal group schemes by Suslin, Friedlander and Bendel [SFB1,SFB2], and arbitrary finite-dimensional cocommutative Hopf algebras by Friedlander and Pevtsova [FPe]. Further recent attempts to generalize the theory have been made to

1 E-mail address: brian@math.uga.edu.
finite-dimensional algebras by Solberg and Snashall [SS] via Hochschild cohomology and to Hecke algebras by Erdmann and Holloway [EH].

For a finite-dimensional cocommutative Hopf algebra $A$ over an algebraically closed field $k$ the cohomology ring $H^*(A,k)$ is a graded commutative finitely generated algebra [FS]. For any finitely generated $A$-module $M$, one can assign a conical subvariety $V_A(M)$ inside the spectrum of the cohomology ring. These support varieties provide a method to introduce the geometry of the spectrum of $H^*(A,k)$ into the representation theory of $A$.

The geometric implications become evident when one considers a reductive algebraic group $G$ over an algebraically closed field $k$ of characteristic $p > 0$ and the $r$th Frobenius kernels $G_r$, $r \geq 1$. It is well known that representations for $G_1$ are equivalent to modules for the restricted enveloping algebra $A := u(g)$ where $g = \text{Lie } G$. In this situation the spectrum of the cohomology ring is homeomorphic to the restricted nullcone [SFB1,SFB2]

$$\mathcal{N}_1(g) = \{ x \in g \mid x^{[p]} = 0 \}.$$  

Moreover, $\mathcal{N}_1(g)$ is a $G$-stable conical subvariety inside the cone of nilpotent elements (nullcone) $\mathcal{N}(g)$. The nullcone $\mathcal{N}(g)$ has been well studied (see [Car,CM,Hum2]) because of its beautiful geometric properties with deep connections to Lie and representation theory.

1.2. Although support varieties are easy to define once the finite generation of cohomology is established, they are often very difficult to compute. In 1987, Jantzen [Jan2] stated a conjecture for reductive groups that the support varieties of the Weyl modules $V(\lambda)$ over $G_1$ are closures of certain Richardson orbits (depending on $\lambda$) when the characteristic of the underlying field is good. Nakano, Parshall and Vella [NPV, Thm. 6.2.1] proved this conjecture. The verification of this conjecture provides a bridge linking the representation theory, cohomology theory and conjugacy class theory of $g$. As an immediate corollary, it is shown that the restricted nullcone is an irreducible variety when $k$ is of good characteristic. In [CLNP], Carlson, Lin, Nakano and Parshall, using techniques in [NPV], calculated $\mathcal{N}_1(g)$ for good primes. This computation was replicated by the authors in [UGA1] using more elementary methods. The authors in [UGA2] determined the restricted nullcone over fields of bad characteristic. It was shown that $\mathcal{N}_1(g)$ is always irreducible but need not be the closure of a Richardson orbit when $p$ is bad. Calculating the support varieties of Weyl modules is a fundamental result in the theory. The calculation for good primes has advanced our understanding for both restricted and non-restricted representations of $g$ (see [GP,BN,CLN,CLNP,NT]).

For the sake of consistency with [NPV], we will compute the support varieties of the induced modules $H^0(\lambda) := \text{ind}_B^G \lambda$. Since $V(\lambda)$ is the contragredient dual of $H^0(-w_0 \lambda)$ it follows that the support variety of $V(\lambda)$ is the same as the support variety of $H^0(-w_0 \lambda)$. In this paper we will compute the support varieties of induced/Weyl modules over fields of bad characteristic.

There are several differences between the good characteristic and bad characteristic settings that should be emphasized. First, unlike the good characteristic situation the orbits/conjugacy classes in bad characteristic need not coincide with the classes in characteristic zero—interest in the unipotent conjugacy classes over fields of small characteristic has recently been revived by Lusztig [Lu2]. Second, the stabilizer subset $\Phi_\lambda$ (defined in Section 1.4) need not be conjugate under the action of the Weyl group $W$ to a subroot system generated by simple roots. We manage to deal with these issues by introducing a new technique involving “constrictors” of orbits (Section 2.7) which works remarkably well with the closure ordering of orbits in bad characteristic. We can also handle the cases when the support varieties are not closures of Richardson orbits.
Our results in conjunction with [NPV, Thm. 6.2.1] give a complete description of the support varieties of induced/Weyl modules over algebraically closed fields of arbitrary positive characteristic.

1.3. Notation

The notation and conventions of this paper will follow those given in [Jan3]. Let \( k \) be an algebraically closed field of characteristic \( p > 0 \), and \( G \) a simple algebraic group defined over \( k \) with \( T \) a maximal torus of \( G \). The root system associated to the pair \((G, T)\) is denoted by \( \Phi \) and identified with a subset of the set of weights \( X(T) \). Let \( \Phi^{+} \) be a set of positive roots and \( \Phi^{-} \) be the corresponding set of negative roots. The set of simple roots determined by \( \Phi^{+} \) is \( \Delta = \{ \alpha_{1}, \ldots, \alpha_{l} \} \). We will use throughout this paper the ordering of simple roots given in [Hum1] following Bourbaki. Let \( B \) be the Borel subgroup relative to \((G, T)\) given by the set of negative roots and let \( U \) be the unipotent radical of \( B \). More generally, if \( J \subseteq \Delta \), let \( P_{J} \) be the parabolic subgroup relative to \(-J\) and let \( U_{J} \) be the unipotent radical of \( P_{J} \). Let \( \Phi_{J} \) be the root subsystem in \( \Phi \) generated by the simple roots in \( J \). Set \( g = \text{Lie} \ G, \ b = \text{Lie} \ B, \ u = \text{Lie} \ U, \ p_{J} = \text{Lie} \ P_{J}, \) and \( u_{J} = \text{Lie} \ U_{J} \).

Let \( \mathbb{E} \) be the Euclidean space associated with \( \Phi \), and the inner product on \( \mathbb{E} \) will be denoted by \( \langle \ , \ \rangle \). Let \( \check{\alpha} \) be the coroot corresponding to \( \alpha \in \Phi \). Set \( \alpha_{0} \) to be the highest short root. Moreover, let \( \rho \) be the half sum of positive roots. The Coxeter number associated to \( \Phi \) is \( h = \langle \rho, \check{\alpha}_{0} \rangle + 1 \).

We denote the set of positive (resp. nonnegative) integers by \( \mathbb{N} \) (resp. \( \mathbb{Z}_{\geq 0} \)). Let \( X(T) \) be the integral weight lattice spanned by the fundamental weights \( \{ \omega_{1}, \ldots, \omega_{l} \} \). The set \( X(T) \) has a partial ordering defined as follows: \( \lambda \geq \mu \) if and only if \( \lambda - \mu \in \sum_{\alpha \in \Delta} \mathbb{Z}_{\geq 0} \alpha \). The set of dominant integral weights is denoted by \( X(T)^{+} \) and the set of \( p^{r} \)-restricted weights is \( X_{r}(T) \). Set \( H^{0}(\lambda) = \text{ind}_{B}^{G} \lambda \) where \( \lambda \) is the one-dimensional \( B \)-module obtained from the character \( \lambda \in X(T)^{+} \) by letting \( U \) act trivially. The Weyl group corresponding to \( \Phi \) is \( W \) and acts on \( X(T) \) via the dot action \( (w \cdot \lambda = w(\lambda + \rho) - \rho \) where \( w \in W, \lambda \in X(T) \).

In this paper we will consider the case when \( p \) is a bad prime for \( \Phi \). A list of bad primes is provided below.

- \( \Phi \) of type \( A_{1} \), no primes;
- \( \Phi \) of type \( B_{1}, C_{1}, D_{1}, p = 2; \)
- \( \Phi \) of type \( E_{6}, E_{7}, F_{4}, G_{2}, p = 2, 3; \)
- \( \Phi \) of type \( E_{8}, p = 2, 3, 5. \)

If the prime \( p \) does not appear on this list then \( p \) is a good prime relative to \( \Phi \).

Let \( \mathcal{N}(g) \) be the irreducible variety (of dimension \(|\Phi|\)) of nilpotent elements of \( g \), which is often called the nullcone. The group \( G \) acts on \( \mathcal{N}(g) \) via the adjoint representation, and \( \mathcal{N}(g) \) has finitely many \( G \)-orbits [Lu1]. For good primes the nilpotent orbits are classified in exactly the same way as over the complex numbers. On the other hand for bad primes the nilpotent orbits are determined in [He,Sp1,Sp2,Sp3,HS]. The conventions in [Law1, Law2] will be employed for the exceptional groups. If \( X \) is the Bala–Carter label for an orbit in characteristic zero which “splits” in characteristic \( p \), then \( X^{(p)} \) will denote the new orbit that arises.

Now view \( G \) as an algebraic group scheme defined over \( \mathbb{F}_{p} \) and let \( F: G \rightarrow G \) be the Frobenius morphism. Set \( G_{r} = \text{Ker} \ F^{r} \) where \( F^{r} \) is the Frobenius map iterated with itself \( r \) times. Let \( F_{|B}: B \rightarrow B \) be the restriction of \( F \) to \( B \), let \( B_{r} = \text{Ker}(F_{|B})^{r} \) and let \( B_{r}T \) be the inverse image of \( T \) under \( (F_{|B})^{r} \). Set
\[ R = \begin{cases} H^2(G_r, k) & \text{if } \text{char } k \neq 2, \\ H^*(G_r, k) & \text{if } \text{char } k = 2. \end{cases} \]

According to [FS], \( R \) is a finitely generated commutative \( k \)-algebra. Furthermore, if \( M \) is a finite-dimensional module for \( G_r \) then \( \text{Ext}^*_G(M, M) \) is a finitely generated module over \( R \). Let \( J_r(M) \) denote the set of elements in \( R \) which annihilate \( \text{Ext}^*_G(M, M) \). Define \( V_G(M) = \text{Maxspec}(R/J_r(M)) \). The affine homogeneous variety \( V_G(M) \) is called the support variety of \( M \). Similarly, if \( M \) is a \( B_r \)-module one can define \( V_{B_r}(M) \). We will mainly be interested in the case when \( r = 1 \), but will state results for arbitrary \( r \) when appropriate.

### 1.4. Motivation

For \( \lambda \in X(T) \), define

\[ \Phi_\lambda = \{ \alpha \in \Phi \mid \langle \lambda + \rho, \tilde{\alpha} \rangle \in \mathbb{Z} \}. \]

Then \( \Phi_\lambda \) is either empty or a root subsystem of \( \Phi \), and when \( p \) is a good prime, there exist \( w \in W \) and \( I \subseteq \Delta \) such that \( w(\Phi_\lambda) = \Phi_I \). The following result was proved by Nakano, Parshall and Vella for good primes [NPV, Thm. 6.2.1, Cor. 6.2.2].

**Theorem.** Let \( G \) be a reductive algebraic group and assume that \( p \) is good. Let \( \lambda \in X(T)_+ \). Choose \( w \in W \) such that \( w(\Phi_\lambda) = \Phi_I \) for some \( I \subseteq \Delta \). Then

(a) \( V_{G_1}(H_0^\lambda) = G \cdot u_I \).
(b) \( \dim V_{G_1}(H_0^\lambda) = |\Phi| - |\Phi_\lambda| \).

The main issue relevant for bad primes is the fact that \( \Phi_\lambda \) need not be conjugate to a root subsystem \( \Phi_I \). This makes formulating a precise conjecture on the support varieties of induced modules in this case somewhat intractable. Nevertheless, one might conjecture that

\[ \dim V_{G_1}(H_0^\lambda) \geq |\Phi| - |\Phi_\lambda| \tag{1.4.1} \]

for all primes. Indeed this is exactly what we will prove. The first step will be to prove the lower bound

\[ \dim V_{G_1}(H_0^\lambda) \geq |\Phi| - |\Phi_\lambda| \tag{1.4.2} \]

for all primes. The next step is to prove a general version of the upper bound [NPV, Cor. 4.5.1]. These results along with our information about the restricted nullcone for bad primes will allow us to compute the support varieties of the induced modules while simultaneously verifying the dimension equality (1.4.1).

Note that our definition of \( \Phi_\lambda \) differs from the stabilizer given in [NPV, §3.4]. For good primes, these two definitions agree, but for bad primes this will lead us to adapt several graded dimension results in [NPV, §3] to our setting.

### 2. General results

#### 2.1. Restricted nullcones

In [UGA2], the authors computed the restricted nullcone \( N_1(\mathfrak{g}) \) over fields of bad characteristic. This result will be used throughout this paper because the support variety of any \( G_1 \)-module is contained in \( N_1(\mathfrak{g}) \).
Theorem (A). Let \( G \) be a simple classical connected algebraic group over \( k \) with \( p = 2 \) a bad prime.

(i) If \( \Phi \) is of type \( B_l \) then \( \mathcal{N}_1(g) = \mathcal{O}(2^1_{2}, 1_1) \).

(ii) If \( \Phi \) is of type \( C_l \) then \( \mathcal{N}_1(g) = \mathcal{O}(2^1_{1}). \)

(iii) If \( \Phi \) is of type \( D_l \) then \( \mathcal{N}_1(g) = \mathcal{O}(2^2_{5}). \)

Theorem (B). Let \( G \) be an exceptional algebraic group with \( p \) a bad prime.

(i) If \( \Phi \) is of type \( E_6 \) then \( \mathcal{N}_1(g) = \mathcal{O}(X) \) where \( X = 2A_2 + A_1 \) (\( p = 3 \)), \( 3A_1 \) (\( p = 2 \)).

(ii) If \( \Phi \) is of type \( E_7 \) then \( \mathcal{N}_1(g) = \mathcal{O}(X) \) where \( X = 2A_2 + A_1 \) (\( p = 3 \)), \( 4A_1 \) (\( p = 2 \)).

(iii) If \( \Phi \) is of type \( E_8 \) then \( \mathcal{N}_1(g) = \mathcal{O}(X) \) where \( X = A_4 + A_3 \) (\( p = 5 \)), \( 2A_2 + 2A_1 \) (\( p = 3 \)), \( 4A_1 \) (\( p = 2 \)).

(iv) If \( \Phi \) is of type \( F_4 \) then \( \mathcal{N}_1(g) = \mathcal{O}(X) \) where \( X = A_1 + \tilde{A}_2 \) (\( p = 3 \)), \( A_1 + \tilde{A}_1 \) (\( p = 2 \)).

(v) If \( \Phi \) is of type \( G_2 \) then \( \mathcal{N}_1(g) = \mathcal{O}(X) \) where \( X = G_2(a_1) \) (\( p = 3 \)), \( A_1 \) (\( p = 2 \)).

The inclusion relations among orbit closures in \( \mathcal{N}_1(g) \) are provided in Section 6.

2.2. Poles and rates of growth

Our first objective is to prove the inequality in (1.4.2). We will adapt the methods used in [NPV, §3] in order to accomplish this. Several of the arguments are also provided here for the sake of completeness and to assist the reader. We should also mention that our argument was inspired by Ostrik [Ost] who proved the inequality in the quantum setting when \( p > h \).

Recall that if \( \{a_n\}_{n \geq 0} \) is a sequence of complex numbers then the rate of growth \( r(a_n) \) of this sequence is the smallest non-negative integer \( d \) such that there exists a positive number \( C \) with the property that

\[
|a_n| \leq C \cdot n^{d-1}
\]

for all \( n > 0 \). By convention, if no such \( d \) exists, then \( r(a_n) = \infty \).

If there is a polynomial \( f(t) \) of degree \( d - 1 \) such that \( a_n = f(n) \) for sufficiently large \( n \) then \( r(a_n) = d \). Furthermore, if \( S_n = |a_0| + \cdots + |a_n| \), then \( r(S_n) = d + 1 \). We state a useful proposition from [NPV] which relates the rate of growth of \( \{a_n\}_{n \geq 0} \) with the poles of the corresponding Poincaré series.

Proposition. Let \( p(t) = \sum_{n=0}^{\infty} a_n t^n \in \mathbb{C}[[t]] \).

(a) If \( p(t) = \frac{f(t)}{(1-t)^d} \) for some positive integer \( d \) and \( f(t) \in \mathbb{C}[t] \) with \( f(1) \neq 0 \), then \( a_n \) is a polynomial in \( n \) of degree \( d - 1 \). Hence, \( r(a_n) = d \).

(b) Assume the poles of \( p(t) \) are roots of unity. If \( e^{i\theta} \) is a pole of order \( \gamma \), then

\[
\gamma \leq r(a_n).
\]

(c) Assume \( p(t) = \frac{f(t)}{(1-t)^r} \) for positive integers \( b, r \) and \( f(t) \in \mathbb{C}[t] \), with \( f(1) \neq 0 \). Fix \( i \), \( 0 \leq i < r \). For \( j \) sufficiently large, \( a_{i+j} \) is a polynomial in \( j \) (say of degree \( d_i - 1 \)).

(d) In (c), let \( d = \max d_i \). Then \( d = r(a_n) \). If \( S_n = |a_0| + \cdots + |a_n| \), then \( r(S_n) = d + 1 \).
2.3. Fix a weight $\Lambda$ and suppose that $M \in \text{mod}(B_r T)$ (the set of finite-dimensional $B_r T$-modules) and all weights of $M$ satisfy $\mu \leq \Lambda$. That is, all weights of $M$ lie in the cone defined by $\Lambda$. If $\mu \leq \Lambda$ then $0 \leq \Lambda - \mu = \sum_{\alpha \in \Delta} n_\alpha \alpha$ where $n_\alpha \in \mathbb{Z}_{\geq 0}$ for $\alpha \in \Delta$. Set $\text{ht}(\Lambda - \mu) = \sum_{\alpha \in \Delta} n_\alpha$. We define the graded dimension of $M$ as

$$\dim_t M = \sum_{\mu \leq \Lambda} (\dim M_\mu) t^{\text{ht}(\Lambda - \mu)}$$

(2.3.1)

where $M_\mu$ is the $\mu$ weight space with respect to $T$. This definition coincides with the principal grading given in [K, §10.8]. According to [K, Prop. 10.10],

$$\dim_t H^0(\Lambda) = \prod_{\alpha \in \Phi^+} \frac{1 - t^{\langle \Lambda + \rho, \tilde{\alpha} \rangle}}{1 - t^{\langle \rho, \tilde{\alpha} \rangle}}.$$  

(2.3.2)

Let $P_r(\mu)$ be the projective cover of the simple $B_r T$-module $L_r(\mu)$ of highest weight $\mu \in X(T)$. Let $M \in \text{mod}(B_r T)$ and let $P_\bullet$ be a minimal projective resolution of $M$ in $\text{mod}(B_r T)$. Upon restriction to $B_r$, this still provides a minimal projective resolution of $M$ as a $B_r$-module. Since $P_\bullet$ is a minimal resolution we have

$$P_n \cong \bigoplus_{\mu \in X_r(T)} \text{Ext}^n_{B_r} (M, \mu) \otimes P_r(\mu)$$

(2.3.4)

as $T$-modules. Note that $\dim_t P_r(\Lambda) = h_r(t)$ and

$$\dim_t P_r(\mu) = t^{\text{ht}(\Lambda - \mu)} h_r(t)$$

(2.3.5)

for $\mu \leq \Lambda$, because $P_r(\mu) \cong \text{coind}^{B_r T}_\mu$ (cf. [NPV, (3.1.6)]).

Let $P_r(\sigma + p^r \nu)$ be a $B_r T$-direct summand of $P_n$ and set $\tau_n = \sigma + p^r \nu$ (with $\sigma \in X_r(T)$ and $\nu \in X(T)$). Since $P_\bullet$ is a minimal resolution it follows that $\tau_n$ is a weight in the radical of $P_{n-1}$. Consequently, $\tau_{n-1} = \tau_n + \beta$ appears in the head of $P_{n-1}$, where $\beta$ is some non-trivial sum of positive roots. Therefore, $\Lambda - \tau_n = \Lambda - \tau_{n-1} + \beta$. Applying heights we see that $\text{ht}(\Lambda - \tau_n) \geq \text{ht}(\Lambda - \tau_{n-1}) + 1$ and iterating this process $n$ times yields

$$\text{ht}(\Lambda - \tau_n) \geq \text{ht}(\Lambda - \tau) + n$$

(2.3.6)

where $\tau$ is a weight in the head of $M$.

Now assuming that all weights $\mu$ of $M$ satisfy $\mu \leq \Lambda$, then the smallest possible height $\text{ht}(\Lambda - \tau)$, where $\tau$ is a weight of $M$, is zero. Hence, in this case $\text{ht}(\Lambda - \tau_n) \geq n$. 
2.4. For a positive integer $d$ let $\Psi_d(t) \in \mathbb{Z}[t]$ be the $d$th cyclotomic polynomial in $\mathbb{Q}[t]$. The polynomials $\Psi_d(t)$ are irreducible over $\mathbb{Q}$. The following theorem extends [NPV, Thm. 3.3.1] which shows that $\dim V_{B_r}(M)$ is related to the order of the poles of the rational function $(\dim_t M)/h_r(t)$.

**Theorem.** Let $M$ be a finite-dimensional $B_r T$ module with all weights of $M$ being less than or equal to some $\Lambda \in X(T)_+$. Let

$$q(t) = \frac{\dim_t M}{h_r(t)} = \frac{f(t)}{(1-t^{p_r})^\gamma g(t)}$$

where $f(t), g(t) \in \mathbb{Q}[t]$ and $\Psi_{p_r}(t) \nmid f(t)g(t)$. Then $\gamma \leq \dim V_{B_r}(M)$.

**Proof.** Under our assumptions one can assume $\gamma \geq 0$ and $\gamma$ is the order of the pole of any primitive $p_r$th root of unity in $q(t)$. Let $P_\bullet$ be a minimal projective resolution of $M$ in the category of $B_r T$ modules. Now express

$$\frac{\dim_t P_n}{h_r(t)} = \sum_m b(m,n)t^m,$$

where each $b(m,n)$ is a non-negative integer.

Since $\dim V_{B_r}(M)$ is the rate of growth of $\{ \text{Ext}^n_{B_r}(M,N) \}$ where $N = \bigoplus_{\mu \in X_r(T)} \mu$ is the direct sum of simple $B_r$-modules (cf. [Ben]), it follows from (2.3.4) and (2.3.5) that for some $C > 0$,

$$\sum_m b(m,n) = \dim \text{Ext}^n_{B_r}(M,N) \leq Cn^{\dim V_{B_r}(M)-1}. \quad (2.4.1)$$

Suppose that $b(m,n) \neq 0$. Then for some $\sigma \in X_r(T)$ and $\nu \in X(T)$, $P_r(\sigma + p_r \nu)$ appears as a direct summand of $P_n$ with $m = \text{ht}(\Lambda - (\sigma + p_r \nu))$. From (2.3.6) one can conclude that if $b(m,n) \neq 0$ then $m \geq n$. Hence,

$$q(t) = \sum_{n=0}^{\infty} (-1)^n \frac{\dim_t P_n}{h_r(t)}.$$

Now we are in the position to follow the line of reasoning given in [NPV, Thm. 3.3.1] directly. We include the argument for the convenience of the reader.

Expand $q(t) = \sum_{i=0}^{\infty} a_it^i$ into a power series. From (2.4.1), it follows that for $i > 0$,

$$S_i = |a_0| + \cdots + |a_i| \leq \sum_{m=0}^{i} \sum_{n=0}^{\infty} b(m,n) = \sum_{m=0}^{i} \sum_{n=0}^{m} b(m,n) \leq \sum_{n=0}^{\infty} Cn^{\dim V_{B_r}(M)-1} \leq D_i^{\dim V_{B_r}(M)}$$

for some $D > 0$. 

From the definition of $h_r(t)$ one can deduce that the poles of $q(t)$ are roots of unity. Let $b$ be the least common multiple of the orders of these poles. Then $q(t) = \frac{m(t)}{(1-p^b)^r}$ for some positive integer $c$ and $m(t) \in \mathbb{C}[t]$. According to Proposition 2.2(c), $q(t) = q_0(t) + \cdots + q_{a-1}(t)$, with $q_i(t) = \sum b_{ij} t^{i+jb}$ with the property that $b_{ij}$ is a polynomial in $j$ of degree $d_i - 1$. Set $d = \max d_i$. Then by Proposition 2.2(d), $r(S_i) = d + 1$ and $r(a_i) = d$. Thus, by (2.4.2), $r(a_i) \leq \dim V_{Br}(M)$. The statement of the theorem now follows by Proposition 2.2(b).

2.5. The following corollary establishes the inequality described in (1.4.2), which improves the lower bound given in [NPV, Cor. 3.4.3].

**Corollary.** Let $\lambda \in X(T)_+$. Then $\dim V_{G_1}(H^0(\lambda)) \geq |\Phi| - |\Phi_\lambda|$.

**Proof.** Recall that for any positive integer $n$, $t^n - 1 = \prod_{d|n} \psi_d(t)$. Set $\Lambda = \lambda$ and $M := H^0(\lambda)$. Consider

$$q(t) = \frac{\dim_t M}{h_1(t)} = \prod_{\alpha \in \Phi^+} \frac{t^{(\lambda + p, \alpha)} - 1}{t^{p(\alpha, \alpha)} - 1}. \quad (2.5.1)$$

Observe that $\psi_p(t)$ divides the numerator exactly $|\Phi^+|$ times and $\psi_p(t)$ divides the denominator exactly $|\Phi^+|$ times. Therefore, by Theorem 2.4 we have

$$\dim V_{B_1}(H^0(\lambda)) \geq |\Phi^+| - |\Phi^+|. \quad (2.5.2)$$

According to [LN], if $M$ is a rational $G$-module then $\dim V_{G_1}(M) = 2 \dim V_{B_1}(M)$. Hence,

$$\dim V_{G_1}(H^0(\lambda)) = 2 \dim V_{B_1}(H^0(\lambda)) \geq 2(|\Phi^+| - |\Phi^+_\lambda|) = |\Phi| - |\Phi_\lambda|. \quad \square$$

2.6. An upper bound

In this section we provide an effective method for forcing the inclusion of the support variety of an induced module into the closure of certain nilpotent orbits; that is, an upper bound on the support variety. The technique involves checking a combinatorial condition which allows one to deduce that the module is projective over regular elements for Levi subalgebras.

For $J \subseteq \Delta$, let $x_J = \sum_{\alpha \in J} x_\alpha$, where $x_\alpha$ is a root vector in the root space $g_\alpha$. The theorem below was proved under the assumption that $p$ is a good prime (see [NPV, Thm. 4.3.1]). The statement of this theorem still remains valid over arbitrary primes because if the regular element $x_\Delta$ is contained in $\mathcal{N}_1(g)$ then $p \geq h$ by [CLNP, UGA2] (the determination of the restricted nullcone). This implies that the $B$-orbit of $x_\Delta$ is dense in $\mathcal{N}_1(b)$. The arguments provided in [NPV, 4.4, 4.5] can then be used to prove the following statement.

**Theorem.** Let $J \subseteq \Delta$ and $\lambda \in X(T)_+$. If $w(\Phi_\lambda) \cap \Phi_J \neq \emptyset$ for all $w \in W$, then $x_J \notin V_{G_1}(H^0(\lambda))$.

2.7. Constrictors

Let $\mathcal{O}$ be an orbit in $\mathcal{N}_1(g)$. The constrictors of $\mathcal{O}$ are the orbits contained in $\mathcal{N}_1(g) - \mathcal{O}$ which are minimal with respect to the closure ordering of orbits in $\mathcal{N}(g)$. The following result will be
used in the next two sections to compute the support varieties of the induced modules. We will utilize Theorem 2.6 in addition to information about the constrictors of orbits.

**Theorem.** Let $\mathcal{O}$ be an orbit in $\mathcal{N}_1(g)$ and $\{\mathcal{O}_1, \mathcal{O}_2, \ldots, \mathcal{O}_s\}$ be the set of constrictors of $\mathcal{O}$. Let $\lambda \in X(T)_+$ and assume that the following conditions are satisfied:

(i) $|\Phi| - |\Phi_\lambda| \geq \dim \mathcal{O}$;
(ii) for $i = 1, 2, \ldots, s$, $\mathcal{O}_i = G \cdot x_{J_i}$ for some $J_i \subseteq \Delta$;
(iii) for $i = 1, 2, \ldots, s$, $w(\Phi_\lambda) \cap \Phi_{J_i} \neq \emptyset$ for all $w \in W$.

Then $V_{G_1}(H^0(\lambda)) = \overline{\mathcal{O}}$.

**Proof.** Conditions (ii) and (iii) along with Theorem 2.6 show that $x_{J_i} \notin V_{G_1}(H^0(\lambda))$ for $i = 1, 2, \ldots, s$. In particular $V_{G_1}(H^0(\lambda)) \cap \mathcal{O}_j = \emptyset$ for $j = 1, 2, \ldots, s$ (by $G$-invariance). If $\mathcal{O}'$ is an orbit in $\mathcal{N}_1(g) - \overline{\mathcal{O}}$ and $V_{G_1}(H^0(\lambda)) \cap \mathcal{O}' \neq \emptyset$ then $\overline{\mathcal{O}'} \subseteq V_{G_1}(H^0(\lambda))$. But, this is impossible since every orbit closure in $\mathcal{N}_1(g) - \overline{\mathcal{O}}$ must contain a constrictor, hence $V_{G_1}(H^0(\lambda)) \cap \mathcal{O}' = \emptyset$. This shows that $V_{G_1}(H^0(\lambda)) \subseteq \overline{\mathcal{O}}$.

Since $\overline{\mathcal{O}}$ is an irreducible variety and $\dim V_{G_1}(H^0(\lambda)) \geq \dim \mathcal{O}$ by (i) and Corollary 2.5 one can deduce that $V_{G_1}(H^0(\lambda)) = \overline{\mathcal{O}}$. □

2.8. Strategy

Suppose that $\lambda \in X(T)_+$. We first observe that $\Phi_\lambda = \Phi_{\lambda+p\nu}$ for any $\nu \in X(T)$ and $\Phi_{w\cdot\lambda} = w^{-1}(\Phi_\lambda)$. This implies that if the conditions of Theorem 2.7 hold for $\lambda$ then they also hold for any $w \cdot \lambda + p\nu \in X(T)_+$ where $w \in W$ and $\nu \in X(T)$. Therefore, it suffices to show that the conditions of Theorem 2.7 hold for representatives in $X(T)_+$ under the dot action of the extended affine Weyl group. These representatives can be chosen in $X_1(T)$.

Given such a representative the first step in our computation is to calculate $|\Phi| - |\Phi_\lambda|$ and find all orbits in $\mathcal{N}_1(g)$ of that dimension. Many times there will be only one such orbit. Certainly the orbit(s) that we consider will satisfy (i) of Theorem 2.7. For each orbit we look at the constrictors (as defined in Section 2.7). It turns out that all such constrictors are of the form $G \cdot x_{J}$ for some $J \subseteq \Delta$ (i.e., an orbit representative is given by a regular Levi element), so condition (ii) is satisfied. For the set of constrictors of a given orbit of dimension $|\Phi| - |\Phi_\lambda|$ we check (using computer calculations in the exceptional cases) whether condition (iii) holds in Theorem 2.7. It turns out that all three conditions of Theorem 2.7 hold for a unique orbit $\mathcal{O}$ and this allows us to deduce that $V_{G_1}(H^0(\lambda)) = \overline{\mathcal{O}}$. In particular, $V_{G_1}(H^0(\lambda))$ is uniquely determined by $\Phi_\lambda$. Once this is verified for all such representatives, we have by the above remarks,

$$V_{G_1}(H^0(\mu)) = V_{G_1}(H^0(w \cdot \mu + p\nu))$$

where $\mu \in X(T)_+$, $w \in W$, $\nu \in X(T)$ and $w \cdot \mu + p\nu \in X(T)_+$.

3. Classical Lie algebras

In this section we compute the support varieties of the induced modules $H^0(\lambda)$ for the classical groups in bad characteristic (i.e., types $B, C, D$ with $p = 2$). We follow the strategy of Section 2.8. We first determine orbit representatives $x_{J}$ for the constrictor orbits which will arise
later. We next show that every orbit of weights under the extended affine Weyl group has a fundamental dominant weight \( \omega_k \) (or 0) as a representative. This significantly simplifies the remaining computations. We use this information to compute the lower bound \(|\Phi| - |\Phi_\lambda|\) of Corollary 2.5, and identify a candidate orbit of that dimension, together with its associated constrictor orbits. Finally we verify condition (iii) of Theorem 2.7.

Throughout this section we let \( N = 2l + 1 \) (resp. \( 2l \), \( 2l \)) in type \( B_l \) (resp. \( C_l \), \( D_l \)).

### 3.1. Nilpotent orbit representatives

The nilpotent orbits in \( g \) have been classified by Hesselink [He]. They are parametrized by pairs consisting of a partition \( \mu \) of \( N \) and an index function \( \chi : I \to \mathbb{Z} \), where \( I \) is the set of (non-zero) parts of \( \mu \). The partition gives, as usual, the sizes of the Jordan blocks for any representative of the orbit.

There is a one-to-one correspondence between nilpotent orbits and pairs \( \mu, \chi \) satisfying the following conditions. Write \( n(m) \) for the multiplicity of \( m \in I \) as a part in \( \mu \).

#### (3.1.1)  
(1) For \( m > k \) in \( I \), \( \chi(m) \geq \chi(k) \) and \( m - \chi(m) \geq k - \chi(k) \).

(2) For \( G = \text{Sp}(N) \) and \( m \in I \):
   (a) \( 0 \leq \chi(m) \leq m/2 \);
   (b) \( \chi(m) = m/2 \) if \( n(m) \) is odd.

(3) For \( G = \text{O}(N) \) and \( m \in I \):
   (a) \( m/2 \leq \chi(m) \leq m \);
   (b) \( \chi(m) = m \) if \( n(m) \) is odd;
   (c) \( \{ m \in I | n(m) \text{ is odd} \} = \{ i, i - 1 \} \cap \mathbb{N} \) for some \( i \in \mathbb{Z} \).

If \( I = \{ m_1 > m_2 > \cdots \} \), Hesselink displays the pair \( \mu, \chi \) as a symbol

\[
\mu_\chi = (m_1^{n(m_1)_{\chi(m_1)}}, m_2^{n(m_2)_{\chi(m_2)}}, \ldots).
\]

Write \( \mathcal{O}(\mu_\chi) \) for the corresponding nilpotent orbit.

**Proposition.** Let \( G = \text{O}(N) \) or \( \text{Sp}(N) \) over a field \( k \) of characteristic 2, and let \( g = \text{Lie}(G) \) have rank \( l \). The table lists certain regular nilpotent elements for Levi subalgebras of \( g \) having type \( A_1 \times \cdots \times A_1 \), and the nilpotent orbits to which they belong.

<table>

</tr>
</tbody>
</table>

In type \( D_l \) when \( l \) is even, \( x_{a_1} + x_{a_3} + \cdots + x_{a_{l-3}} + x_{a_{l-1}} \) and \( x_{a_1} + x_{a_2} + \cdots + x_{a_{l-3}} + x_{a_l} \) are both representatives for the \( \text{O}(2l) \)-orbit with symbol \( (2^l_1) \), which lie in distinct \( \text{SO}(2l) \)-orbits. (Here \( \text{SO}(2l) \) is by definition the component of the identity in \( \text{O}(2l) \).)
Proof. We first treat the case \( G = \text{Sp}(N) \) with \( N = 2l \). Following Hesselink, let \( V \) be an \( N \)-dimensional vector space over \( k \) equipped with a non-degenerate bilinear form \( \beta \) satisfying \( \beta(v, v) = 0 \) for all \( v \in V \). Then \( G \) is the group of automorphisms of \( V \) leaving \( \beta \) invariant. Fix \( x \in g \) with \( x \) nilpotent. For each \( i \in \mathbb{N} \cup \{0\} \) define a quadratic form \( q_i : V \to k \) by \( q_i(v) = \beta(x^{i+1}v, x^i v) \). An extension to \( \mathbb{N} \) of the index function given at the beginning of Section 3.1 is defined by

\[
\chi(m) = \min\{i \geq 0: q_i|_{\ker(x^m)} = 0\}. \tag{3.1.2}
\]

In particular, \( \chi(1) = 0 \), and if \( x^2 = 0 \) then \( q_1 = 0 \), and

\[
\chi(2) = \begin{cases} 0 & \text{if } q_0 = 0; \\ 1 & \text{otherwise}. \end{cases} \tag{3.1.3}
\]

We take the matrix of \( \beta \) to be

\[
K = \begin{pmatrix} 0 & 1 & \cdots & 1 \\ \vdots & \ddots & \ddots & \vdots \\ 1 & \cdots & 0 & 0 \end{pmatrix}
\]

so that \( x \in g \iff x^tK = Kx \iff Kx^tK = x \). The matrix \( x' := Kx^tK \) is obtained from \( x \) by transposing across the antidiagonal, so \( x \in g \) if and only if \( x \) is symmetric about the antidiagonal.

We can take a Cartan subalgebra to be the diagonal matrices in \( g \). Then the simple root vectors can be chosen to be

\[
x_{\alpha_i} = \begin{cases} E_{i,i+1} + E_{N-i,N+1-i} & \text{if } i < l; \\ E_{l,l+1} & \text{if } i = l \end{cases}
\]

(\( E_{ij} \) are the matrix units). Consider

\[
x = x_{\alpha_1} + x_{\alpha_3} + \cdots + x_{\alpha_{2r-1}} \quad \text{where } 2r - 1 < l.
\]

Then \( x \) is already in Jordan canonical form, with block sizes given by the partition \((2^r, 1^{N-4r})\).

It is elementary to check that \( \beta(xv, v) = 0 \) for all \( v \in V \), so that \( q_0 \equiv 0 \) and hence by (3.1.3), \( \chi(2) = 0 \). Thus \( x \) belongs to the orbit \( \mathcal{O}(2^r, 1^{N-4r}) \).

If

\[
x = x_{\alpha_1} + x_{\alpha_{2r-2}} + \cdots + x_{\alpha_{2r}}
\]

then again \( x \) is in Jordan form, with block sizes \((2^{2r+1}, 1^{N-4r-2})\), but now \( q_0(v) = \beta(xv, v) = v_{n+1}^2 \neq 0 \) so \( \chi(2) = 1 \). Thus \( x \) belongs to the orbit \( \mathcal{O}(2^{2r+1}, 1_0^{N-4r-2}) \).

For the orthogonal case, let \( V \) be an \( N \)-dimensional vector space over \( k \), equipped with a quadratic form \( q \) and a bilinear form \( \beta \) satisfying \( \beta(v, w) = q(v + w) - q(v) - q(w) \) for all \( v, w \in V \). We assume that \( V \) is non-degenerate in the sense of [He]. Then \( G = O(N) \) is the algebraic group of automorphisms of \( V \) leaving \( q \) invariant. Fix \( x \in g \) with \( x \) nilpotent. For each \( i \in \mathbb{N} \cup \{0\} \) define a quadratic form \( q_i : V \to k \) by \( q_i(v) = q(x^i v) \). The index function \( \chi \) is defined as in (3.1.2). Then \( \chi(1) = 1 \), and when \( x^2 = 0 \), \( \chi(2) \) is given by

\[
\chi(2) = \begin{cases} 1 & \text{if } q_1 = 0; \\ 2 & \text{otherwise}. \end{cases} \tag{3.1.4}
\]
For \( v = (v_1, \ldots, v_N) \), we may take \( q(v) = v_1v_N + v_2v_{N-1} + \cdots \), so that the matrix of \( \beta \) is \( K \) when \( N = 2l \) is even, and is \( K_0 = K - E_{l+1,l+1} \) when \( N = 2l + 1 \) is odd. A matrix \( x \) belongs to \( g \) if and only if \( \text{tr} \, x = 0 \) and \( \beta(xv, v) = 0 \) for all \( v \in V \). When \( N \) is even the second condition is equivalent to \( x \) being symmetric about the antidiagonal, with antidiagonal elements all zero. If \( N \) is odd, say \( N = 2l + 1 \), then \( x \) has the block form

\[
x = \begin{pmatrix}
A & 0 & C \\
w & 0 & u \\
B & 0 & A'
\end{pmatrix}
\tag{3.1.5}
\]

where \( A, B, C \) are \( l \times l \), \( w \) and \( u \) are \( 1 \times l \), \( B \) and \( C \) are symmetric about the antidiagonal with antidiagonal elements all zero, and \( A' \) denotes \( A \) transposed across the antidiagonal. In either case we may take a Cartan subalgebra consisting of the diagonal matrices in \( g \), and simple root vectors

\[
x_{\alpha_i} = \begin{cases}
E_{i,i+1} + E_{N-i,N+1-i} & \text{if } i < l; \\
E_{l+1,l+2} & \text{if } i = l \text{ in type } B_l; \\
E_{l-1,l+1} + E_{l,l+2} & \text{if } i = l \text{ in type } D_l.
\end{cases}
\]

Assume \( N = 2l + 1 \). Arguing similarly to the symplectic case, one finds that \( x_{\alpha_1} + x_{\alpha_3} + \cdots + x_{\alpha_{2r-1}} \) with \( 2r - 1 < l \) lies in the orbit \( O(2^{2r}, 1^{N-4r}) \), while \( x_{\alpha_l} + x_{\alpha_{l-2}} + \cdots + x_{\alpha_{2r}} \) with \( r \geq 0 \) has \( q_1(v) = q(xv) = v_{l+2}^2 \neq 0 \) so it is in the orbit \( O(2^{2r+1}, 1^{N-4r-2}) \).

Assume \( N = 2l \). Using the same techniques as in types \( B_l \) and \( C_l \), it is straightforward to check that \( x_{\alpha_1} + x_{\alpha_3} + \cdots + x_{\alpha_{2r-1}} \) with \( 2r - 1 < l \) lies in the orbit \( O(2^r, 1^{N-4r}) \). Similarly when \( l \) is even, \( x_{\alpha_1} + x_{\alpha_3} + \cdots + x_{\alpha_{l-1}} + x_{\alpha_l} \) is in the orbit \( O(2^l) \). Consider

\[
x = x_{\alpha_{l-1}} + x_{\alpha_l} = E_{l-1,l} + E_{l-1,l+1} + E_{l,l+2} + E_{l+1,l+2}.
\]

Note that \( x : e_{l+2} \mapsto e_l + e_{l+1} \mapsto 0, \ e_l \mapsto e_{l-1} \mapsto 0 \) (where \( \{e_i : 1 \leq i \leq N \} \) is the standard basis of \( V \)); this shows that \( x \) has Jordan block sizes \( (2^l, 1^{N-4}) \). And \( q_1(v) = q(xv) = v_{l+2}^2 \neq 0 \) so \( x \) is in the orbit \( O(2^l, 1^{N-4}) \).

To complete the proof it remains only to verify the final claim of the proposition. Assume \( N = 2l \) with \( l \) even. We have shown that \( x = x_{\alpha_1} + x_{\alpha_3} + \cdots + x_{\alpha_{l-1}} + x_{\alpha_l} \) and \( y = x_{\alpha_1} + x_{\alpha_3} + \cdots + x_{\alpha_{l-1}} + x_{\alpha_l} \) both lie in the \( O(N) \)-orbit \( O(2^l) \). By [He], this orbit splits into two distinct \( SO(N) \)-orbits. Also by [He], the group \( O(N) \) is generated by the reflections \( r_w \), for \( w \in V \) with \( q(w) \neq 0 \), given by

\[
r_w(v) = v - \beta(v, w)q(w)^{-1}w,
\]

while \( SO(N) \) consists of the products of an even number of such reflections. Let \( w = e_l + e_{l+1} \), with \( q(w) = 1 \). Then \( r_w \) interchanges \( e_l \) and \( e_{l+1} \) while fixing all other \( e_i \). Thus, conjugation by \( r_w \) interchanges \( x_{\alpha_{l-1}} \) and \( x_{\alpha_l} \), and fixes all other \( x_{\alpha_i} \). In particular, \( r_w \) is an element of \( O(N) - SO(N) \) which takes \( x \) to \( y \). Since \( SO(N) \) has index 2 in \( O(N) \), it follows that \( x \) and \( y \) must belong to the two different \( SO(N) \) orbits in the \( O(N) \) orbit \( O(2^l) \). \( \square \)
3.2. Generic W-orbits in $X_1(T)$

Let $\Phi$ be of type $X_l$, where $X = B, C, \text{ or } D$, and let $p = 2$. In view of the strategy in Section 2.8, we consider the action of $W$ on $X(T)/pX(T)$, which we identify with $X_1(T)$ by taking $p$-restricted parts of weights. In this subsection and the next, we will classify the $W$-orbits in $X_1(T)$. For convenience in stating the results, we work here with the ordinary (not the dot) action of $W$; the $\rho$ shifts will be inserted later. And for simplicity of notation, we write equalities when we really mean congruences modulo $pX(T)$.

Set $\omega_0 = 0$ and $S_k = W(\omega_k)$ for $0 \leq k \leq l$. We plan to show that $X_1(T) = \bigcup_{k=0}^{l} S_k$. To do this, we first identify $S_1$ explicitly as a set of $l$ elements in each type. We then show that for $k \leq m$ (a certain integer depending on the type, defined below), $S_k$ consists of sums of $k$ distinct elements of $S_1$. We determine when an element of $S_k$ can be written in more than one way as such a sum, and also when $S_k = S_j$. In the next subsection we will identify $\bigcup_{k=m+1}^{l} S_k$. These data allow us to count $|\bigcup_{k=0}^{l} S_k| = 2^l = |X_1(T)|$.

We fix the integer $m$ as follows:

$$m = \begin{cases} \ l - 1, & X = B, \\ \ l, & X = C, \\ \ l - 2, & X = D. \end{cases}$$

We will repeatedly use formulas (modulo $pX(T)$) for $s_i(\omega_j) = \omega_j - \delta_{ij}\alpha_l$. The following formulas are easily checked by taking the inner product of each side with $\delta_{kk}$ for all $k$:

$$s_i(\omega_l) = \begin{cases} \omega_{l-2} + \omega_{l-1}, & i = l - 1, \text{ type } B_l; \\ \omega_l, & i = l, \text{ type } C_l; \\ \omega_{l-3} + \omega_{l-2} + \omega_{l-1} + \omega_l, & i = l - 2, \text{ type } D_l; \\ \omega_{l-2} + \omega_{l-1}, & i = l - 1, \text{ type } D_l; \\ \omega_{l-2} + \omega_l, & i = l, \text{ type } D_l; \\ \omega_{l-1} + \omega_l + \omega_{l+1}, & \text{otherwise} \end{cases} \tag{3.2.1}$$

with the convention that $\omega_0 = \omega_{l+1} = 0$. The following formula follows immediately:

$$s_{k-1}s_{k-2} \cdots s_1(\omega_l) = \omega_{k-1} + \omega_k \quad \text{for } 1 \leq k \leq m. \tag{3.2.2}$$

The remaining elements of $S_1$ are determined case-by-case, again using (3.2.1). If $X = C$ then $s_1s_{l-1} \cdots s_1(\omega_1) = \omega_{l-1} + \omega_l$, which is already accounted for in $S_1$, so we get no new elements. If $X = B$ then $s_{l-1}s_{l-2} \cdots s_1(\omega_1) = \omega_{l-1}$, from which we can produce no additional new elements. Finally if $X = D$ then $s_{l-2}s_{l-3} \cdots s_1(\omega_1) = \omega_{l-2} + \omega_{l-1} + \omega_l$, and $s_{l-1}s_{l-2} \cdots s_1(\omega_1) = s_{l-2}s_{l-3} \cdots s_1(\omega_1) = \omega_{l-1} + \omega_l$, from which we can produce no additional new elements. We summarize these results.

**Proposition.** Let $\Phi$ be of type $X_l$ where $X = B, C, \text{ or } D$, and let $p = 2$. The $W$-orbit of $\omega_1$ in $X_1(T)$ consists of $l$ distinct elements, as follows:

$$S_1 = \{ \omega_1, s_1(\omega_1), s_2s_1(\omega_1), \ldots, s_{l-1}s_{l-2} \cdots s_1(\omega_1) \}$$

$$= \begin{cases} \{ \omega_1, \omega_1 + \omega_2, \ldots, \omega_{l-2} + \omega_{l-1}, \omega_{l-1} \}, & X = B; \\ \{ \omega_1, \omega_1 + \omega_2, \ldots, \omega_{l-2} + \omega_{l-1} + \omega_l \}, & X = C; \\ \{ \omega_1, \omega_1 + \omega_2, \ldots, \omega_{l-2} + \omega_{l-1} + \omega_l \}, & X = D. \end{cases}$$

Moreover, for $i \leq l$, $s_{i-1}s_{i-2} \cdots s_1(\omega_1)$ does not involve any $\omega_j$ with $j < i - 1$. 

Next we have a technical lemma which allows us to write sums of \( k \) elements of \( S_1 \) as elements of \( S_k \).

**Lemma.** Let \( k \leq m \) and \( 1 \leq i_1 < i_2 < \cdots < i_k \leq l \) be positive integers. Then

\[
s_{i_1-1}s_{i_1-2}\cdots s_1(\omega_1) + s_{i_2-1}s_{i_2-2}\cdots s_1(\omega_1) + \cdots + s_{i_k-1}s_{i_k-2}\cdots s_1(\omega_1) = (s_{i_1-1}s_{i_1-2}\cdots s_1)(s_{i_2-1}s_{i_2-2}\cdots s_2)\cdots (s_{i_k-1}s_{i_k-2}\cdots s_k)(\omega_k). 
\]

**Proof.** We use induction on \( k \). If \( k = 1 \) the result is trivial. In general, substitute \( \omega_k = \omega_{k-1} + s_{k-1}s_{k-2}\cdots s_1(\omega_1) \) from (3.2.1) (recall we are working mod 2) on the right hand side. Observe that \( s_i, s_{r-1}, \cdots, s_j \) fixes \( s_{i-1}s_{i-2}\cdots s_1(\omega_1) \) for \( r < i - 1 < l \) (by the last statement of the Proposition), so the right hand side of the above equation is equal to

\[
(s_{i_1-1}s_{i_1-2}\cdots s_1)(s_{i_2-1}s_{i_2-2}\cdots s_2)\cdots (s_{i_k-1}s_{i_k-2}\cdots s_k)(\omega_{k-1}) + s_{i_k-1}s_{i_k-2}\cdots s_1(\omega_1).
\]

Since \( s_i \) fixes \( \omega_{k-1} \) for \( r > k - 1 \), this is equal to

\[
(s_{i_1-1}s_{i_1-2}\cdots s_1)(s_{i_2-1}s_{i_2-2}\cdots s_2)\cdots (s_{i_{k-1}-1}s_{i_{k-1}-2}\cdots s_{k-1})(\omega_{k-1}) + s_{i_k-1}s_{i_k-2}\cdots s_1(\omega_1).
\]

The result now follows by induction. \( \square \)

**Theorem.** For \( 1 \leq k \leq m \), \( S_k \) consists of all sums of \( k \) distinct elements of \( S_1 \). The expression for an element of \( S_k \) as such a sum is unique, except when \( X = B \) or \( D \) and \( k = 1/2 \), when every element of \( S_k \) can be written in precisely two ways as a sum of \( k \) distinct elements of \( S_1 \). The orbits \( S_k \) are distinct, except that \( S_k = S_{l-k} \) for \( 1 \leq k \leq l - 1 \) in type \( B \), and for \( 2 \leq k \leq l - 2 \) in type \( D \).

**Proof.** Let \( \tilde{S}_k \) denote the set of sums of \( k \) distinct elements of \( S_1 \). According to the proposition, every \( \mu \in \tilde{S}_k \) can be expressed as on the left side of the equation in the lemma. Then \( \mu \in S_k \), by the right side of that equation. To prove the reverse inclusion, notice that \( \omega_k \) is the sum of the first \( k \) elements of \( S_1 \), in the order listed in the proposition. Hence any \( W \)-translate of \( \omega_k \) is the sum of the \( W \)-translates of these \( k \) elements, which are in turn distinct elements of \( S_1 = W(\omega_1) \).

A similar argument shows that the number of ways of writing \( \omega_k \) as a sum of distinct elements of \( S_1 \) is the same as the number of such ways of writing every element of \( S_k \). In type \( C \) it is clear from the explicit description of \( S_1 \) that \( \omega_1 + (\omega_1 + \omega_2) + \cdots + (\omega_{l-1} + \omega_l) \) is the only way of so writing \( \omega_k \). In type \( B \) there is another way: \( (\omega_k + \omega_{k+1}) + (\omega_{k+1} + \omega_{k+2}) + \cdots + (\omega_{l-1}) \), a sum of \( l - k \) elements. In type \( D \) there is also a second way of writing \( \omega_k \), namely \( (\omega_k + \omega_{k+1}) + (\omega_{k+1} + \omega_{k+2}) + \cdots + (\omega_{l-2} + \omega_{l-1} + \omega_l) + (\omega_{l-1} + \omega_l) \), also a sum of \( l - k \) elements. This shows that \( \tilde{S}_k = \tilde{S}_{l-k} \) in types \( B \) and \( D \), and hence that \( S_k = S_{l-k} \) (provided, in type \( D \), that \( k \geq 2 \), since \( m = l - 2 \)). These second expressions for \( \omega_k \) are in \( \tilde{S}_k \) (and hence every element of \( S_k \) has two realizations as a sum of \( k \) elements of \( S_1 \)) if and only if \( k = l/2 \). \( \square \)

3.3. Special \( W \)-orbits in \( X_1(T) \)

Here we use a different technique to identify \( \bigcup_{k=m+1}^{l} S_k \). In type \( C_l \) there is nothing to do since \( m = l \). In type \( B_l \) we need only identify \( S_l \).
Proposition (A). In type $B_l$, $\bigcup_{k=0}^{l-1} S_k = \{ \lambda \in X_1(T) \mid \langle \lambda, \alpha_l \rangle = 0 \}$ and $S_l = \{ \lambda \in X_1(T) \mid \langle \lambda, \alpha_l \rangle = 1 \}$.

Proof. Since, by (3.2.1), the coefficients of $\omega_l$ in $\lambda$ and $s_i(\lambda)$ are the same for every simple reflection $s_i$, it is clear that $L_0 := \{ \lambda \in X_1(T) \mid \langle \lambda, \alpha_l \rangle = 0 \}$ and $L_1 := \{ \lambda \in X_1(T) \mid \langle \lambda, \alpha_l \rangle = 1 \}$ are $W$-invariant. In particular, $S_l \subset L_1$ and $S_k \subset L_0$ for $0 \leq k \leq l - 1$. In fact, by Theorem 3.2 we have

$$|S_l| = \frac{l-1}{2} \sum_{k=1}^{l-1} \binom{l}{k} = \frac{l-1}{2} (2^l - 2) = 2^{l-1} - 1 = |L_0|,$$

so that

$$L_0 = \bigcup_{k=0}^{l-1} S_k. \quad (3.3.1)$$

To prove that $L_1 \subset S_l$, we first claim that $\omega_{l-i} + \omega_l \in S_l$ for $1 \leq i \leq l - 1$. We prove this by induction on $i$. Since $s_i(\omega_l) = \omega_{l-1} + \omega_l$ and $s_i s_{l-1} s_l(\omega_l) = \omega_{l-2} + \omega_l$ by (3.2.1), the claim is true for $i = 1$ and $2$. Assume it is true for some $i \geq 2$. Use (3.2.1) to check that

$$s_{l-2} s_{l-3} \cdots s_{l-i} (\omega_{l-i} + \omega_l) = \omega_{l-(i+1)} + \omega_{l-2} + \omega_{l-1} + \omega_l.$$

Apply $s_{l-1}$ and finally $s_l$ to obtain $\omega_{l-(i+1)} + \omega_l$, as required to complete the induction.

Now let $\lambda \in L_1$. Then $\lambda = \mu + \omega_l$ where $\mu \in L_0$. Then by (3.3.1), $\mu \in S_k$ for some $0 \leq k < l$. So we may write $\mu = w(\omega_k)$ for some $w \in W$. By Lemma 3.2, we may in fact assume that $w \in \{s_1, \ldots, s_{l-1}\}$. Then $w(\omega_l) = \omega_l$ so $\lambda = \mu + \omega_l = w(\omega_k) + \omega_l = w(\omega_k + \omega_l) \in S_l$, by the claim. \[\square\]

Finally in type $D_l$ we need to identify $S_{l-1} \cup S_l$.

Proposition (B). In type $D_l$, $\bigcup_{k=0}^{l-2} S_k = \{ \lambda \in X_1(T) \mid \langle \lambda, \alpha_{l-1} \rangle = \langle \lambda, \alpha_l \rangle \}$ and $S_{l-1} \cup S_l = \{ \lambda \in X_1(T) \mid \langle \lambda, \alpha_{l-1} \rangle \neq \langle \lambda, \alpha_l \rangle \}$. When $l$ is odd, $S_{l-1} = S_l$.

Proof. Since, by (3.2.1), no simple reflection changes the coefficient of exactly one of $\omega_{l-1}, \omega_l$ in a decomposition of $\lambda \in X_1(T)$ as a linear combination of fundamental weights, the sets $L_0 := \{ \lambda \in X_1(T) \mid \langle \lambda, \alpha_{l-1} \rangle = \langle \lambda, \alpha_l \rangle \}$ and $L_1 := \{ \lambda \in X_1(T) \mid \langle \lambda, \alpha_{l-1} \rangle \neq \langle \lambda, \alpha_l \rangle \}$ are $W$-invariant. In particular, $S_{l-1} \cup S_l \subset L_1$ and $S_k \subset L_0$ for $0 \leq k \leq l - 2$. A counting argument similar to the one in the previous proposition shows that

$$L_0 = \bigcup_{k=0}^{l-2} S_k. \quad (3.3.2)$$

To prove that $L_1 \subset S_{l-1} \cup S_l$, we first claim that $\omega_{l-i} + \omega_l \in S_l$ for $i$ even, $2 \leq i < l$, and $\omega_{l-i} + \omega_{l-1} \in S_l$ for $i$ odd, $3 \leq i < l$. (The same statements, with $\omega_l$ and $\omega_{l-1}$ interchanged, hold for $S_{l-1}$.) Begin the induction on $i$ with the computations $s_i(\omega_l) = \omega_{l-2} + \omega_l$ and $s_i s_{l-2} s_l(\omega_l) = \omega_{l-3} + \omega_{l-1}$. The inductive step follows from the computation
Lemma 3.2, we may assume 

\[ s_{l-1} s_{l-2} s_{l-3} \cdots s_{l-i} (\omega_l - i + \omega_l) = \omega_l - (i+1) + \omega_l - 1 \]

(and similarly interchanging \(\omega_l\) and \(\omega_l - 1\), and using \(s_l\) in place of \(s_{l-1}\)).

Now let \(\lambda \in L_1\). Then without loss of generality \(\lambda = \mu + \omega_l\) where \(\mu \in L_0\). (The other possibility is \(\lambda = \mu - \omega_l\), but these are congruent modulo \(2\omega_l\) and we are working in \(X(T)/2X(T)\).) Then by (3.3.2), \(\mu \in S_l\) for some \(0 \leq k \leq m\). So \(\mu = w(\omega_k)\) for some \(w \in W\), but in fact by Lemma 3.2, we may assume \(w \in \{s_1, \ldots, s_{l-1}\}\). Then \(w(\omega_l) = \omega_l\) so \(\lambda = \mu + \omega_l = w(\omega_k) + \omega_l = w(\omega_k + \omega_l) \in S_l \cup S_{l-1}\), by the claim.

Finally we prove the last statement of the proposition. When \(l\) is odd, we have \(l-1\) even, and so by the claim of the second paragraph with \(i = l - 1\), \(\omega_1 + \omega_l \in S_l\). But \(s_{l-1} s_{l-2} \cdots s_1 (\omega_1 + \omega_l) = \omega_l - 1\), so \(\omega_l - 1 \in S_l\) and thus \(S_{l-1} \subset S_l\). The reverse inclusion follows by symmetry, so we have \(S_{l-1} = S_l\) as desired. \(\square\)

**Theorem.** Let \(\Phi\) be of type \(X_l\) where \(X = B, C,\) or \(D\), and \(p = 2\). Then \(X_1(T) = \bigcup_{k=0}^l S_k\).

**Proof.** First suppose \(X = C\). Then by Theorem 3.2, the sets \(S_k\) are disjoint subsets of \(X_1(T)\) for \(0 \leq k \leq l\), and \(|S_k| = \binom{l}{k}\). Thus \(|\bigcup_{k=0}^l S_k| = 2^l = |X_1(T)|\). The theorem follows.

If \(X = B\) or \(D\) the theorem follows from the two previous propositions, since \(X_1(T) = L_0 \cup L_1\). \(\square\)

**3.4. Computation of \(|\Phi| - |\Phi_{\lambda}|\)**

Define \(r\) as follows:

\[
r = \begin{cases} 
  l - 2k, & \Phi = B_l, C_l, D_l, 1 \leq k \leq \frac{l}{2}, \\
  -l + 2k, & \Phi = B_l, D_l, \frac{l}{2} < k \leq l - 1, \\
  -l + 2k - 1, & \Phi = C_l, \frac{l}{2} < k \leq l.
\end{cases}
\]

When \(r\) is defined in this way and \(k\) is in the defined range, one has \(0 \leq l - r \leq l\). This will make our labelling of partitions make sense later in Section 3.6. We now calculate \(|\Phi| - |\Phi_{\lambda}|\) for classical Lie algebras. Recall the results of the previous two subsections for the values of \(k\) which index the \(W\)-orbits in \(X_1(T)\).

**Proposition.** Let \(\Phi\) be of type \(X_l\) where \(X = B, C,\) or \(D\). Let \(\lambda = \omega_k - \rho\), and define \(r\) as above. Then

\[
|\Phi| - |\Phi_{\lambda}| = \begin{cases} 
  l^2 - r^2, & X = B_l, 1 \leq k \leq \frac{l}{2}, \\
  l^2 + l, & X = B_l, k = l, \\
  l^2 + l - r^2 - r, & X = C_l, 1 \leq k \leq l, \\
  l^2 - r^2, & X = D_l, 1 \leq k \leq \frac{l}{2}, \\
  l^2 - l, & X = D_l, k = l - 1, l.
\end{cases}
\]

**Proof.** Set \(\lambda = \omega_k - \rho\). Let us first assume that for types \(B_l\) and \(D_l\), we have \(1 \leq k \leq \frac{l}{2}\) and for type \(C_l\), \(1 \leq k \leq l\). Then \(\Phi_{\lambda} = \{\alpha \mid \langle \omega_k, \alpha \rangle \in 2\mathbb{Z}\}\). Express \(\alpha = n_1 \hat{\alpha}_1 + n_2 \hat{\alpha}_2 + \cdots + n_l \hat{\alpha}_l\). If \(\alpha \in \Phi_{\lambda}\) then \(n_k = 0, \pm 2\). If \(n_k = 0\) then \(\alpha\) is in the root subsystem \(A_{k-1} \times X_{l-k}\). Moreover, the number of roots such that \(n_k = \pm 2\) is \(k(k+1)\) (resp. \(k(k-1), (k-1)(k-2)\)) when \(X = B\) (resp. \(C, D\)). This gives \(|\Phi| - |\Phi_{\lambda}| = 4lk - 4k^2\) when \(X = B\) or \(D\) and \(4lk - 4k^2 + 2k\) when \(X = C\). Substituting \(r\) as defined before the proposition yields the desired results.
On the other hand, for type $B_l$ (resp. $D_l$) when $k = l$ (resp. $k = l - 1, l$), $\Phi_\lambda$ is isomorphic to $A_{l-1}$. Therefore, $|\Phi| - |\Phi_\lambda| = 2l^2 - l(l - 1) = l^2 + l$ (resp. $2(l^2 - l) - l(l - 1) = l^2 - l$).

### 3.5. Dimensions of orbits

In [UGA2], the restricted nullcone $N_1(g)$ was calculated. The Hasse diagram for $N_1(g)$ was deduced from work of Großer [Gr] and Spaltenstein [Sp1] or can be obtained by using [UGA2, Thm. 2.3]. We provide this information in Section 6. The dimensions of the orbits in $N_1(g)$ can be computed from formulas given by Hesselink [He, Thm. 4.4]. This data will be essential for our computations so we have recorded it below.

<table>

### 3.6. Supports of induced modules

The following theorem presents the computation of the supports of the induced modules $H^0(w \cdot \lambda)$, $w \cdot \lambda \in X(T)_+$ when $G$ is $O(N)$ or $Sp(N)$ and char $k = 2$. By Theorem 3.3 and the remarks in Section 2.8, it suffices to consider $\lambda$ of the form $\omega_k - \rho$.

**Theorem.** Let $G = O(2l + 1)$, $Sp(2l)$, or $O(2l)$ be a classical group with root system $\Phi$ of type $B_l$, $C_l$ or $D_l$ and assume that char $k = 2$. Let $r$ be as defined in Section 3.4. Let $\lambda = \omega_k - \rho$. The support varieties of the induced modules $H^0(w \cdot \lambda)$ where $w \cdot \lambda \in X(T)_+$ are given in the following table.

| $\Phi$ | $k$ | Constrictors | $|\Phi| - |\Phi_\lambda|$ | $V_{G_1}(H^0(w \cdot \lambda))$ |
|--------|-----|--------------|-----------------|-----------------------------|
| $B_l$  | $1 \leq k \leq \frac{1}{2}$ | $O(2_{1}^{l-r+2}, 1_{1}^{2r-3})$, $O(2_{2}, 1_{1}^{2l-1})$ | $l^2 - r^2$ | $O(2_{2}^{l-r}, 1_{1}^{2r+1})$ |
|        | $l$ | $O(2_{2}, 1_{1}^{2l-1})$ | $l^2 + l$ | $O(2_{2}, 1_{1})$ |
| $C_l$  | $1 \leq k \leq \frac{1}{2}$ | $O(2_{0}^{l-r}(r-2), 1_{0}^{2(r-2)})$, $O(2_{1}^{l-r}(r-1), 1_{0}^{2(r-1)})$ | $l^2 + l - r^2 - 1$ | $O(2_{1}^{l-r}, 1_{0}^{2r})$ |
| $C_l$  | $\frac{1}{2} < k \leq l$ | $O(2_{0}^{l-r}(r-1), 1_{0}^{2(r-1)})$ | $l^2 + l - r^2 - r$ | $O(2_{1}^{l-r}, 1_{0}^{2r})$ |
| $D_l$  | $1 \leq k \leq \frac{1}{2}$ | $O(2_{1}^{l-r}(r-2), 1_{1}^{2(r-2)})$ | $l^2 - r^2$ | $O(2_{2}^{l-r}, 1_{1}^{2r})$ |
|        | $l$ | $O(2_{2}, 1_{1}^{2(r-2)})$ | $l^2 - l$ | $O(2_{1}^{l-r}, 1_{1}^{2r})$ |
| $D_l$  | $l$ | $O(2_{1}, 1_{1}^{2(r-2)})$ | $l^2 - l$ | $O(2_{1}^{l-r}, 1_{1}^{2r})$ |
Proof. In Proposition 3.4, we calculated \(|\Phi| - |\Phi_\lambda|\) for an element \(\lambda = \omega_k - \rho\) in a typical \(W\)-orbit on \(X_1(T)\). According to Section 3.5, there exists an orbit in \(N_{1}(g)\) of dimension equal to \(|\Phi| - |\Phi_\lambda|\). The orbits considered are given by \(O := O(2_{1}^{l-r+2}, 1_{1}^{r-3})\) (resp. \(O_{1}^{2_{1}^{l-r} - 1}, 1_{0}^{2_{1}^{r}}\)) when \(\Phi\) is of type \(B_l\) (resp. \(C_l, D_l\)); we postpone the cases \(k = l\) in \(B_l\), \(k = l - 1, l\) in \(D_l\). From the Hasse diagrams given in Section 6, one can easily determine the constrictors for these orbits (which are given in the statement of the theorem).

From Proposition 3.1, it follows that the constrictors are all of the form \(G \cdot x_J\) where \(J \subseteq \Delta\). The results of this theorem will now follow from Theorem 2.7, if we verify condition (iii), which says that \(w(\Phi_\lambda) \cap \Phi_J \neq \emptyset\) for all \(w \in W\). Note that \(w^{-1}(\Phi_\lambda) = \Phi_{w \cdot \lambda}\); indeed,

\[\langle w \cdot \lambda + \rho, \tilde{a}\rangle = \langle w(\omega_k), \tilde{a}\rangle.\]

Since \(\Phi_J \cong A_1 \times A_1 \times \cdots \times A_1\), our task is equivalent to proving that for every \(w \in W\), \(2\langle w(\omega_k), \tilde{a}\rangle\) for some \(a \in J\).

We will proceed case by case. For type \(B_l\), we have \(N = 2l + 1\). Assume \(1 \leq k \leq l/2\), so \(r = l - 2k\). Then \(O(2_{1}^{l-r+2}, 1_{1}^{r-3}) = O(2^{2(k+1)}, 1_{1}^{N-4(k+1)})\). Recall that \(S_1 = \{\omega_1, \omega_1 + \omega_2, \ldots, \omega_{l-2} + \omega_{l-1}, \omega_{l-1}\}\). An element in the \(W\) orbit of \(\omega_k\) must be the sum of \(k\) distinct elements of \(S_1\). Consider such an element of the form

\[w(\omega_k) = n_1 \omega_1 + n_2 (\omega_1 + \omega_2) + \cdots + n_{l-1} (\omega_{l-2} + \omega_{l-1}) + n_l \omega_{l-1}\]

where \(0 \leq n_j \leq 1\) for all \(j\). Observe that \(J = \{a_1, a_3, \ldots, a_{2(k+1)-1}\}\) so \(|J| = k + 1\).

Suppose that \(\langle w(\omega_k), \tilde{a}_{2j-1} \rangle \equiv 1 \mod 2\) for \(j = 1, 2, \ldots, k + 1\). Then the \(k + 1\) terms \(n_1 + n_2, n_3 + n_4, n_5 + n_6, n_2(k+1) - 1 + n_2k\) must all be equal to 1. But, this implies that there are \(k + 1\) distinct elements of \(S_1\) in the expression of \(w(\omega_k)\), which is a contradiction. Hence, \(2\langle w(\omega_k), \tilde{a}_{2j} \rangle\) for some \(j = 1, 2, \ldots, 2(k + 1) - 1\). For the other constrictor \(O(2_{1}^{l-r}, 1_{1}^{l-r})\), we have \(J = \{a_1\}\) according to the table in Proposition 3.1. Since \(w(\omega_k)\) never contains \(\omega_1\) as a summand (because of our description of \(S_k\)), it follows that \(\langle w(\omega_k), \tilde{a}_1 \rangle = 0\) for all \(w \in W\). The case when \(k = l\) can be deduced immediately because the restricted nullcone is the closure of \(O(2_{1}^{l}, 1_{1}^{l-1})\) (an irreducible variety). The variety has dimension \(l^2 + l\) which is also a lower bound for the dimension of the support variety (i.e., \(|\Phi| - |\Phi_\lambda|\)).

For type \(C_l\) (resp. \(D_l\)) when \(r = l - 2k\) (i.e., \(0 \leq k \leq l/2\)) one has \(N = 2l\) and

\[O(2_{0}^{l-r+2}, 1_{0}^{2r-4}) = O(2_{0}^{2(k+1)}, 1_{0}^{N-4(k+1)}), \quad O(2_{1}^{l-r+1}, 1_{0}^{2r-2}) = O(2_{1}^{2k+1}, 1_{0}^{N-4k-2})\]

(resp. \(O(2_{1}^{l-r+2}, 1_{1}^{2r-4}) = O(2_{1}^{2(k+1)}, 1_{1}^{N-4(k+1)})\)). The same argument as for type \(B_l\) can be used to verify that for \(w \in W\), \(2\langle w(\omega_k), \tilde{a}_{2j} \rangle\) for some \(a \in J\).

For type \(C_l\) when \(r = -l + 2k - 1\) (i.e., \(l/2 < k \leq l\)) we have \(O(2_{0}^{l-r-1}, 1_{0}^{2(r-1)}) = O(2_{0}^{2(l-k-1)}, 1_{0}^{N-4(l-k-1)})\). The tables in Proposition 3.1, we have \(|J| = l - k + 1\). Since \(l - 1 < k\) we have \(|J| = l - k + 1 \leq k\) with equality holding if and only if \(k = \frac{l+1}{2}\). If \(|J| < k\) then we can use the same argument as in the type \(B_l\) case to deduce that condition (iii) of Theorem 2.7 holds. On the other hand, if \(k = \frac{l+1}{2}\) then \(l\) must be odd and \(l - (r - 1) = 2(l - k + 1) = l + 1\). But in the case when \(l\) is odd the only allowable orbits \(O(2_{0}^{l-s}, 1_{0}^{2s})\) occur when \(l - s < l\). That is, there are no constrictors in this case.
The remaining cases for $D_l$ when $k = l - 1$, $l$ can be easily verified using arguments similar to those given in the preceding paragraphs. □

4. Exceptional Lie algebras

4.1. In this section we compute the support varieties for the induced modules for exceptional Lie algebras. The strategy follows the one outlined in Section 2.8. Let us illustrate this with the following example.

Example. Let $\Phi = G_2$ and $p = 3$. The positive roots with their corresponding coroots are given in the following table. Note that $\Delta = \{\alpha_1, \alpha_2\}$ where $\alpha_1$ is the short root.

<table>
<thead>
<tr>
<th>root</th>
<th>coroot</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\alpha_1$</td>
<td>$\tilde{\alpha}_1$</td>
</tr>
<tr>
<td>$\alpha_2$</td>
<td>$\tilde{\alpha}_2$</td>
</tr>
<tr>
<td>$\alpha_1 + \alpha_2$</td>
<td>$\tilde{\alpha}_1 + 3\tilde{\alpha}_2$</td>
</tr>
<tr>
<td>$2\alpha_1 + \alpha_2$</td>
<td>$2\tilde{\alpha}_1 + 3\tilde{\alpha}_2$</td>
</tr>
<tr>
<td>$3\alpha_1 + \alpha_2$</td>
<td>$\tilde{\alpha}_1 + \tilde{\alpha}_2$</td>
</tr>
<tr>
<td>$3\alpha_1 + 2\alpha_2$</td>
<td>$\tilde{\alpha}_1 + 2\tilde{\alpha}_2$</td>
</tr>
</tbody>
</table>

Recall that $\Phi_\lambda = \{\alpha \in \Phi \mid \langle \lambda + \rho, \alpha \rangle \in p\mathbb{Z}\}$. The restricted region $X_1(T)$ contains nine weights and their stabilizers are computed below.

<table>
<thead>
<tr>
<th>$\lambda$</th>
<th>$\lambda + \rho$</th>
<th>$\Phi_\lambda$</th>
</tr>
</thead>
<tbody>
<tr>
<td>(0, 0)</td>
<td>(1, 1)</td>
<td>${\pm(3\alpha_1 + 2\alpha_2)}$</td>
</tr>
<tr>
<td>(1, 0)</td>
<td>(2, 1)</td>
<td>${\pm(3\alpha_1 + \alpha_2)}$</td>
</tr>
<tr>
<td>(2, 0)</td>
<td>(3, 1)</td>
<td>${\pm\alpha_1, \pm(\alpha_1 + \alpha_2), \pm(2\alpha_1 + \alpha_2)}$</td>
</tr>
<tr>

</table>

One can verify that there are 3 $W$-orbits in $X_1(T)$ under the dot action of the extended affine Weyl group, namely, $\{(0, 0), (1, 0), (0, 1), (1, 1), (0, 2), (1, 2)\}$, $\{(2, 0), (2, 1)\}$, and $\{(2, 2)\}$. The classes have stabilizer $\Phi_\lambda$ isomorphic to $A_1$, $A_2$ and $\Phi$ respectively.

First assume that $\Phi_\lambda$ is isomorphic to $A_1$. Then $|\Phi| - |\Phi_\lambda| = 10$. The restricted null-cone $N_1(g) = \overline{O(G_2(a_1))}$ by Theorem 2.1(B)(v), an irreducible 10-dimensional variety. Hence, $V_{G_1}(H^0(\lambda)) = \overline{O(G_2(a_1))}$ by Corollary 2.5.

Next assume that $\Phi_\lambda$ is isomorphic to $A_2$. In this case $|\Phi| - |\Phi_\lambda| = 6$. There are two 6-dimensional $G$-orbits in $N_1(g)$. Consider $O = O(A_1)$ and its constrictor $O_1 = O(A_1)$ as in Theorem 2.7. Condition (i) is satisfied because $\dim O = 6$. Moreover, condition (ii) holds because $O(A_1) = G \cdot x_{a_1}$. Finally, condition (iii) is satisfied by inspecting the table above for the weights (2, 0) and (2, 1). Hence, $V_{G_1}(H^0(\lambda)) = \overline{O(A_1)}$ by Theorem 2.7.
When $\Phi_\lambda = \Phi$ then $\lambda = (2, 2)$ and $H^0((2, 2))$ is the Steinberg module for $G_1$. This module is projective so $V_{G_1}(H^0(\lambda)) = \{0\}$.

4.2. For the exceptional groups the computation of $V_{G_1}(H^0(\lambda))$ follows the paradigm given in the preceding example. With the help of GAP [Sch], we are able to compute the dot action of $W$ on $X_1(T)$ (identified with $X(T)/pX(T)$). This allows us first to determine the $W$-orbits on $X_1(T)$. Next for a given orbit representative $\lambda$, we identify a potential $G$-orbit of dimension $|\Phi| - |\Phi_\lambda|$ with constrictors $\{O_1, O_2, \ldots, O_s\}$ having the form $G \times J_i$ for $i = 1, 2, \ldots, s$.

Since

$$w(\Phi_\lambda) = \Phi_{w\lambda} = \{\alpha \in \Phi: \langle w \cdot \lambda + \rho, \tilde{\alpha} \rangle \in p\mathbb{Z}\} = \{\alpha \in \Phi: \langle w(\lambda + \rho), \tilde{\alpha} \rangle \in p\mathbb{Z}\},$$

we can again use GAP, to compute the ordinary $W$ action on $\lambda + \rho$ to determine $w(\Phi_\lambda)$. Finally, this allows us to check that $w(\Phi_\lambda) \cap \Phi_i \neq \emptyset$ for $i = 1, 2, \ldots, s$. Our GAP programs are available on the web at http://www.math.uga.edu/~nakano/vigre/vigre.html.

The following tables record our results. In the leftmost column, we give an orbit representative in $X_1(T)$ of $X(T)$ under the extended affine Weyl group. Note our results show that $V_{G_1}(H^0(\lambda)) = V_{G_1}(H^0(w \cdot \lambda + p\nu))$ for all $\lambda, w \cdot \lambda + p\nu \in X(T)_+$ where $w \in W$ and $\nu \in X(T)$.

5. Applications

In this section we prove several consequences of our support variety computations.

5.1. Dimension equality

Here we prove the dimension equality conjecture stated earlier as (1.4.1).

**Theorem.** Let $G$ be a simple algebraic group defined over an algebraically closed field of characteristic $p > 0$. Let $\lambda \in X(T)_+$. Then $\dim V_G(H^0(\lambda)) = |\Phi| - |\Phi_\lambda|$.

**Proof.** For $p$ good this is Theorem 1.4(b). For $p$ bad it follows by observation from the tables in Sections 3 and 4. □
5.2. Irreducibility

For induced modules we can now show that their supports are always irreducible varieties.

**Theorem.** Let $G$ be a simple algebraic group defined over an algebraically closed field of characteristic $p > 0$. Let $\lambda \in X(T)_+$. Then $V_{G_1}(H^0(\lambda))$ is an irreducible variety.

**Proof.** For $p$ good this follows from Theorem 1.4(a). It is also true for $p$ bad since, from the tables in Sections 3 and 4, $V_{G_1}(H^0(\lambda))$ is always the closure of a single $G$-orbit. \qed

5.3. Realization of orbit closures

An open problem from [FP] is: For a simple algebraic group $G$, which $G$-stable, closed, conical subvarieties of $N_1(g)$ can be realized as $V_{G_1}(M)$ for some $G$-module $M$? Because the support of a direct sum is the union of the supports, it is enough to determine which $G$-orbit closures can be realized. In [Jan1,Jan2], Jantzen showed that all orbit closures can be realized in type $A$ and in type $B_2$ (when $p \neq 2$). It follows from [CLNP] that when $p$ is good, the closure of every Richardson orbit in $N_1(g)$ can be realized as the support variety of an induced module. Recently, Nakano and Tanisaki [NT] have proved that when $p$ is good, with the possible exception of a few non-Richardson orbits in type $E$, all other orbit closures can be realized.

We will employ the ideas used in [NT] with some modifications. Assume that $\tilde{\rho}: G \to \text{GL}(V)$ is a representation such that the differential $\rho: g \to \text{gl}(V)$ satisfies the property that $\text{Ker} \rho \cap N(g) = \{0\}$ (here we are also viewing $\rho: G_1 \to \text{GL}(V)$ via the equivalence between restricted representations of $g$ and representations of $G_1$). For any finite-dimensional $\rho(G_1)$-module $M$, we have

$$V_{\text{GL}(V)_1}(M) \cap \rho(g) = V_{\rho(G_1)}(M).$$

Now $M$ becomes a $G_1$-module by composing with $\rho$. Furthermore, $\rho$ induces a natural map $\rho^*: V_{G_1}(M) \to V_{\rho(G_1)}(M)$ which is surjective. This map is injective because $\text{ker} \rho \cap N(g) = \{0\}$. Hence,

$$V_{\text{GL}(V)_1}(M) \cap \rho(g) \cong V_{G_1}(M). \quad (5.3.1)$$

This isomorphism will be used to realize orbit closures as support varieties of $G$-modules.

**Theorem.** Assume that $p$ is a bad prime for a simple algebraic group $G$. Then the closure of every $G$-orbit in $N_1(g)$ is realized as $V_{G_1}(M)$ for some $G$-module $M$, with the following possible exceptions.

1. Type $C_1$: $O(2k^2/n-k)$ for $k \in \mathbb{N}$ even ($p = 2$).
2. Type $F_4$: $O(\tilde{A}_1)$ ($p = 2$).
3. Type $G_2$: $O(\tilde{A}_1)$ ($p = 3$).

**Proof.** We use the following principle [UGA1, Prop. 2.4]. Assume $\rho: G \to \text{GL}(V)$ is a representation satisfying $\text{Ker} \rho \cap N(g) = \{0\}$. Given a $G$-orbit $O \subset N(g)$, we identify $O$ with $\rho(O)$
(and similarly for $\overline{O}$), and let $\lambda(O)$ be the Jordan block partition associated with $\rho(O)$. Let $O_{\lambda(O)}$ denote the corresponding $\text{GL}(V)$ orbit in $\mathfrak{gl}(V)$. Then

$$\overline{O_{\lambda(O)}} \cap \rho(g) = \bigcup O', \quad (5.3.2)$$

where the union is over all $G$-orbits $O' \subseteq N_1(g)$ which are maximal with respect to $\leq$ (the inclusion of orbit closures) and satisfy $\lambda(O') \subseteq \lambda(O)$ (where $\subseteq$ is the dominance ordering on partitions). In particular, if

$$O' \not\subseteq O \Rightarrow \lambda(O') \not\subseteq \lambda(O), \quad (5.3.3)$$

then $\overline{O_{\lambda(O)}} \cap \rho(g) = \overline{O}$. In this case, by [NT] and (5.3.1) there is a $\text{GL}(V)$-module $M$ such that

$$\overline{O} = \overline{O_{\lambda(O)}} \cap \rho(g) = V_{\text{GL}(V)}(M) \cap \rho(g) = V_{G_1}(M|_{G_1}),$$

whence $\overline{O}$ is realized as a support variety of a $G$-module. In any case there is at most one orbit $O'$ besides $O$ on the right side of (5.3.2).

Begin with the exceptional groups and let $p$ be the adjoint representation. Using the tables of adjoint partitions associated to the $G$-orbits in $N_1(g)$ from [UGA2, §6] along with the Hasse diagrams giving the order $\preceq$ (see Section 6), we find that there are four cases where (5.3.3) does not hold (and $\overline{O}$ is not already realized as the support of an induced module). These are tabulated below.

<table>
<thead>
<tr>
<th>Type</th>
<th>$p$</th>
<th>$O$</th>
<th>$O'$</th>
<th>$\lambda(O)$</th>
<th>$\lambda(O')$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$F_4$</td>
<td>2</td>
<td>$O(\tilde{A}_1)$</td>
<td>$O(A_1)$</td>
<td>$(2^{16}, 1^{20})$</td>
<td>$(2^{16}, 1^{20})$</td>
</tr>
<tr>
<td>$F_4$</td>
<td>3</td>
<td>$O(A_2 + \tilde{A}_1)$</td>
<td>$O(A_1 + \tilde{A}_2)$</td>
<td>$(3^{16}, 2^2)$</td>
<td>$(3^{16}, 2^2)$</td>
</tr>
<tr>
<td>$G_2$</td>
<td>2</td>
<td>$O(A_1)$</td>

<td>$O(A_1)$</td>
<td>$(3^3, 1^5)$</td>
<td>$(3, 2^4, 1^3)$</td>
</tr>
</tbody>
</table>

But we can investigate these same orbits $O$ under the minimal representation $\rho$, using the orbit representatives in [UGA2, §5] and MAGMA [BC,BCP]. The Jordan block partitions are given in the next table. (Note that in $F_4$, $p = 3$ we have replaced $O' = A_1 + \tilde{A}_2$ by the smaller orbit $\tilde{A}_2$.)

<table>
<thead>
<tr>
<th>Type</th>
<th>$p$</th>
<th>$O$</th>
<th>$O'$</th>
<th>$\lambda(O)$</th>
<th>$\lambda(O')$</th>
</tr>
</thead>
<tbody>

<td>3</td>
<td>$O(\tilde{A}_1)$</td>
<td>$O(A_1)$</td>
<td>$(3, 2^2)$</td>
<td>$(2^2, 1^3)$</td>
</tr>
</tbody>
</table>

In the two middle rows of the table, $\lambda(O') \not\subseteq \lambda(O)$, so by the discussion at the beginning of the proof, $\overline{O}$ is realized as a support variety in those two cases, leaving $\tilde{A}_1$ in $F_4$, $p = 2$ and in $G_2$, $p = 3$ as the only exceptional orbits possibly not realized as support varieties of $G$-modules in bad characteristic.
For the classical groups, let $\rho$ be the standard representation $V$ with dim $V = N$. Assume first that we are in type $B_l$, where $N = 2l + 1$. The orbit closures not realized as support varieties of induced modules are parametrized by symbols $\mu_\chi = (2^k, 1^{N-2k})$, $k \geq 1$. Recall that the associated Jordan block partition for the minimal representation is obtained from $\mu_\chi$ by deleting the subscripts $\chi$; i.e., it is simply $\mu$. Observe from the Hasse diagram that condition (5.3.3) is satisfied for these orbits. Thus they are all realized as supports of restrictions to $G$ of $\text{GL}(N)$-modules.

Next consider type $D_l$, where $N = 2l$. The orbit closures not realized as support varieties of induced modules are parametrized by symbols $\mu_\chi = (2^k, 1^{N-2k})$, $2 \leq k \leq l - 2$, $k$ even. Here condition (5.3.3) is not satisfied, but we can use another trick. Assume for definiteness that $l$ is even and $G = O(2l)$. There are $G$-modules $M$ and $N$ whose support varieties are $\overline{O(2_1^i)}$ and $\overline{O(2_2^{l-2}, 1_1^4)}$, respectively. Now by a basic property of support varieties,

$$V_{G_1}(M \otimes N) = V_{G_1}(M) \cap V_{G_1}(N) = \overline{O(2_1^{l-2}, 1_1^4)}.$$ 

Iterating this process, we realize all the remaining orbit closures in type $D$. The argument is identical, with a shift in indices, if $l$ is odd. If $G = SO(2l)$ and $l$ is even then the $O(2l)$-orbit $\overline{O(2_1^i)}$ splits into a union of two $G$-orbits, both of whose closures are support varieties of induced $G$-modules, and both of which contain $\overline{O(2_1^{l-2}, 1_1^4)}$, so the same argument works. □

**Remark.** In type $C$ the argument used for type $B$ does not apply because each “unrealized” orbit is dominated (in the closure ordering) by an orbit having the same partition. And the argument used for type $D$ does not work because we do not know that $\overline{O(2_0^{l-\varepsilon}, 1_0^2 \varepsilon)}$ is realized (where $\varepsilon = 0$ if $l$ is even and $\varepsilon = 1$ if $l$ is odd). However, if that orbit were realized, then all the remaining ones in type $C$ would be, too, by the same tensor product construction used in type $D$.

### 5.4. Richardson orbits

When $p$ is a good prime, it follows from the solution to the Jantzen conjecture on support varieties [NPV] that $V_{G_1}(H^0(\lambda))$ is the closure of a Richardson orbit, and every Richardson orbit closure in $\mathcal{N}_1(\mathfrak{g})$ is realized in this fashion. We now consider to what extent these statements are true for bad primes.

**Theorem.** Let $G$ be a simple algebraic group defined over an algebraically closed field of bad characteristic $p$. Let $\mathcal{O}$ be a Richardson orbit in $\mathcal{N}_1(\mathfrak{g})$. Then there exists $\lambda \in X(T)_+$ such that $V_{G_1}(H^0(\lambda)) = \overline{\mathcal{O}}$, except when $\mathcal{O} = \overline{O(2_2^2, 1_1^{2l-3})}$ in type $B_l$.

**Proof.** Recall that $\mathcal{O}$ is Richardson if and only if $\overline{\mathcal{O}} = G \cdot u_J$ for some subset $J \subset \Delta$. Also $\dim G \cdot u_J = 2 \dim u_J = |\Phi| - |\Phi_J|$. The zero orbit is trivially Richardson (corresponding to $J = \emptyset$), and is also the support variety of the Steinberg module, so we assume henceforth that $\mathcal{O}$ is not the zero orbit and $J \neq \emptyset$.

Assume first that $G$ is classical, so $p = 2$. The formula $(x + y)^{[2]} = x^{[2]} + [x, y] + y^{[2]}$ (cf. [NPV, Section 6.3]) implies that $u_J \subset \mathcal{N}_1(\mathfrak{g})$ if and only if $u_J$ is abelian. One checks that $u_J$ is abelian (in characteristic 2) if and only if $\Delta - J$ is a single simple root at an “end” of the Dynkin diagram (i.e., a simple root $\alpha$ such that $(\alpha, \beta) \neq 0$ for exactly one other simple root $\beta$). Comparing $|\Phi| - |\Phi_J|$ (computed using, for instance, [Hum1, Table 12.2.1]) for these $J$ with the dimensions of the orbits from Hesselink (see Section 3), there is always a unique orbit of the
correct dimension. The orbit parameters for the nonzero Richardson orbits are given in the next table.

<table>
<thead>
<tr>
<th>Type</th>
<th>Richardson Orbits</th>
</tr>
</thead>
<tbody>
<tr>
<td>$B_l$</td>
<td>$O(2^l, 1^2l^{-3})$, $O(2^l, 1^l)$</td>
</tr>
<tr>
<td>$C_l$</td>
<td>$O(2^l, 1^2l^{-4})$, $O(2^l)$</td>
</tr>
<tr>
<td>$D_{l, l}$ even</td>
<td>$O(2^l, 1^2l^{-4})$, $O(2^l)$</td>
</tr>
<tr>
<td>$D_{l, l}$ odd</td>
<td>$O(2^l, 1^2l^{-4})$, $O(2^l, 1^2l^{-1}, 1^2)$</td>
</tr>
</tbody>
</table>

(Recall that for $l$ even, the $O(2l)$ orbit $O(2^l)$ splits into two $SO(2l)$ orbits; these are both Richardson.) The theorem now follows in the classical cases by comparison with the circled orbits in Figs. 1 and 2.

Now assume $G$ is exceptional. The Richardson orbits in characteristic zero are given by Hirai in [Hi]. None of these orbits (in $N_1(g)$) “split” in bad characteristic; therefore the Richardson orbits in characteristic $p$ are given by the same parameters. The list of nontrivial Richardson orbits in $N_1(g)$ is given in the table on the following page.

Fig. 1. $O(2l + 1)$, $Sp(2l)$, $O(2l)$ for $l$ even ($N = 2l + 1, 2l, 2l$, respectively).
Fig. 2. $O(2l + 1)$, $Sp(2l)$, $O(2l)$ for $l$ odd ($N = 2l + 1, 2l, 2l$, respectively).

<tr>
<td>$G_2$</td>
<td>$\mathcal{O}(G_2(a_1))$</td>
</tr>
</tbody>
</table>

Comparison with Figs. 3–7 shows that the closures of all these orbits arise as support varieties of induced modules.  

**Remark.** It is clear from the data that, in contrast to the situation when $p$ is good, many non-Richardson orbit closures arise as support varieties of induced modules when $p$ is bad.
6. Hasse diagrams

In Figs. 1–7, we provide the Hasse diagrams for $\mathcal{N}_1(\mathfrak{g})$ when $k$ is a field of bad characteristic for $\Phi$. The orbits whose closures are support varieties of induced/Weyl modules are circled (cf. Sections 3.6 and 4.2).

7. VIGRE Algebra Group at the University of Georgia

This project was initiated during Spring Semester 2004 under the Vertical Integration of Research and Education (VIGRE) Program sponsored by the National Science Foundation (NSF) at
Fig. 5. $E_8$ for $p = 2$ (left), $p = 3$ (center), and $p = 5$ (right).

the Department of Mathematics at the University of Georgia (UGA). We would like to acknowledge the NSF grant DMS-0089927 for its financial support of this project. The VIGRE Algebra Group consists of 4 faculty members, 3 postdoctoral fellows and 5 graduate students. The group was led in Spring 2004 by David J. Benson, Brian D. Boe and Daniel K. Nakano. During Summer 2004, Leonard Chastkofsky directed a group of the students (Bergonio, Platt, and Wright)
who completed the computations for this project. The email addresses of the members of the group are given below.

Faculty:
- David J. Benson bensondj@maths.abdn.ac.uk
- Brian D. Boe brian@math.uga.edu
- Leonard Chastkofsky lenny@math.uga.edu
- Daniel K. Nakano nakano@math.uga.edu

Postdoctoral Fellows:
- Jo Jang Hyun jhjo@sogang.ac.kr
- Jonathan Kujawa kujawa@math.uga.edu
- Nadia Mazza n.mazza@maths.abdn.ac.uk

Graduate Students:
- Philip Bergonio pbergonio@math.uga.edu
- Bobbe Cooper bcooper@math.uga.edu
- Jeremiah Hower jhower@math.uga.edu
- Kenyon J. Platt platt@math.uga.edu
- Caroline Wright cwright@math.uga.edu
